### Dynamic panel data models. Nickell's Bias. Anderson-Hsiao estimator. Arellano-Bond estimator. System GMM estimator.

Jakub Mućk SGH Warsaw School of Economics

## Dynamic panel data models

#### Dynamic linear panel data model:

$$y_{it} = \gamma y_{it-1} + x'_{it}\beta + u_{it}, \tag{1}$$

where

• 
$$u_{it} = \mu_i + \varepsilon_{it}$$
 and  $\varepsilon_{it} \sim \mathcal{N}(0, \sigma_{\varepsilon}^2)$ ,

- $\triangleright \gamma$  is the autoregressive parameter,
- ▶  $y_{it-1}$  is the lagged dependent variable,
- $x_{it}$  is the vector of independent variables.

JAKUB MUĆK ADVANCED APPLIED ECONOMETRICS DYNAMIC PANEL DATA MODELS DYNAMIC

æ

#### Dynamic linear panel data model:

$$y_{it} = \gamma y_{it-1} + x'_{it}\beta + u_{it}, \tag{1}$$

where

• 
$$u_{it} = \mu_i + \varepsilon_{it}$$
 and  $\varepsilon_{it} \sim \mathcal{N}(0, \sigma_{\varepsilon}^2)$ ,

- $\triangleright$   $\gamma$  is the autoregressive parameter,
- ▶  $y_{it-1}$  is the lagged dependent variable,
- $x_{it}$  is the vector of independent variables.
- Remarks:
  - We assume that  $y_{it}$  is the stable (conditional on  $x_{it}$ ) process  $\implies |\gamma| < 1$ . In other words, the effect of idiosyncratic shock ( $\varepsilon_{it}$ ) dies out.
  - The independent variables  $(x_{it})$  are assumed to be strictly exogenous.
  - $\mu_i$  is the individual-specific (random or fixed) effect.
  - Each observation can be written as:

$$y_{it} = \gamma^t y_{i0} + \sum_{j=0}^t \gamma^j \beta' x_{it-j} + \frac{1-\gamma^t}{1-\gamma} \mu_i + \sum_{j=0}^{t-1} \gamma^j u_{it-j},$$
(2)

where  $y_{i0}$  is the (non-stochastic) initial value.

- The demeaning transformation used to get the within estimator *new* creates new independent variables that are correlated with the error term. As a result, the standard OLS estimator is inconsistent.
- General intuition:
  - The within estimator for the panel AR(1) model:

$$y_{it} - \bar{y}_i = (\mu_i - \mu_i) + \gamma \left( y_{it-1} - \bar{y}_{i-1} \right) + \left( \varepsilon_{it} - \bar{\varepsilon}_i \right), \tag{3}$$

where  $\bar{y}_{i-1} = 1/(T-1) \sum_{t=2}^{T} y_{it-1}$ .

- ▶ The mean of the lagged dependent variable  $(\bar{y}_{i-1})$  is correlated with  $\bar{\varepsilon}_i$  even if the error term is not autocorrelated. The average  $\bar{\varepsilon}_i$  contains the lagged error term  $\varepsilon_{it-1}$  and, therefore, it is correlated with  $y_{it-1}$ .
- Taking the probability limit (plim) of the FE estimator (as  $N \to \infty$ ):

$$plim\hat{\gamma}^{FE} = \gamma + \frac{\frac{1}{NT} (y_{it-1} - \bar{y}_{i-1}) (\varepsilon_{it} - \bar{\varepsilon}_i)}{\frac{1}{NT} (y_{it-1} - \bar{y}_{i-1})^2}$$
(4)

it can be observed that the correlations between the lagged dependent variable  $(\bar{y}_{i-1})$  and error term will lead to inconsistency of the OLS estimator.

- Nickell's (1981) bias. The small T bias of the FE estimator as  $N \to \infty$ :  $\operatorname{plim}\left(\hat{\gamma}^{FE} - \gamma\right) = -\frac{(1+\gamma)}{T}\left(1 - \frac{1}{T}\frac{1-\gamma^{T}}{1-\gamma}\right)\left[1 - \frac{1}{T} - \frac{2\gamma}{(1-\gamma)T}\left(1 - \frac{1}{T}\frac{1-\gamma^{T}}{1-\gamma}\right)\right]^{-1}$ (5)
- The bias of the FE estimator depends on T as well as  $\gamma$ .
- For *reasonably* large T it can be approximated:

$$\operatorname{plim}\left(\hat{\gamma}^{FE} - \gamma\right) \approx -\frac{(1+\gamma)}{T-1} \tag{6}$$

SGH

5/21

• but when T = 2 then

$$\operatorname{plim}\left(\hat{\gamma}^{FE} - \gamma\right) \approx -\frac{(1+\gamma)}{2} \tag{7}$$

• The bias in the dynamic fixed effect model is caused by elimination of the individual-specific effect from each observation. It creates a correlation of order 1/T between explanatory variables and error term.

• Consider the RE AR(1) model:

$$y_{it} = \gamma y_{it-1} + \varepsilon_{it} + \mu_i, \tag{8}$$

where  $\varepsilon_{it} \sim \mathcal{N}(0, \sigma_{\varepsilon}^2)$  and  $\mu_{it} \sim \mathcal{N}(0, \sigma_{\mu}^2)$ .

- In the RE model, the quasi-demeaning also leads to correlation between the transformed lagged dependent variable  $(\tilde{y}_{it-1} = y_{it-1} - \theta \bar{y}_{i-1})$  and the transformed error term  $(\tilde{\varepsilon}_{it} = \varepsilon_{it} - \theta \bar{\varepsilon}_i)$ . Therefore, the RE estimates will be biased.
- For t-1 the dependent variable:

$$y_{it-1} = \gamma y_{it-2} + \varepsilon_{it-1} + \mu_i, \tag{9}$$

also depends on the random individual-specific effect. If so, then the assumption that the individual effects are independent of the explanatory variable (in our case also  $y_{it-1}$ ) is not satisfied and

$$\mathbb{E}\left(\mu_i | y_{it-1}\right) \neq 0. \tag{10}$$

• The FD AR(1) estimator:

$$y_{it} - y_{it-1} = (\mu_i - \mu_i) + \gamma \left( y_{it-1} - y_{it-2} \right) + \varepsilon_{it} - \varepsilon_{it-1}$$
(11)

is also biased.

• To illustrate the bias of the FD estimator it's useful to recall  $y_{i,t-1}$ .

$$y_{it-1} = \gamma y_{it-2} + \varepsilon_{it-1} + \mu_i + \varepsilon_{it-1}. \tag{12}$$

SGH

7 / 21

• In the (12)  $y_{it-1}$  depends on the error term  $\varepsilon_{it-1}$ . At the same time, in the (11)  $y_{it-1}$  is the explanatory variable and the error term, given by  $\varepsilon_{it} - \varepsilon_{it-1}$ , contains the lagged error term from the non-transformed model. Therefore, the lagged dependent variable is correlated with the error term also in the FD model.

JAKUB MUĆK ADVANCED APPLIED ECONOMETRICS DYNAMIC PANEL DATA MODELS DYNAMIC PANEL DATA MODELS

- To illustrate the magnitude of the Nickell's bias we run the MC simulations.
- Let's assume that the true DGP (data generating process) is a simple panel AR(1) process:

$$y_{it} = \gamma y_{it-1} + u_{it}, \tag{13}$$

where the error component is quite standard:

$$u_{it} = \mu_i + \varepsilon_{it} \tag{14}$$

where 
$$\mu_i \sim \mathcal{N}(0, \sigma_{\mu}^2)$$
 and  $\varepsilon_{it} \sim \mathcal{N}(0, \sigma_{\varepsilon}^2)$ .

- We will consider the FE estimator.
- The MC settings:
  - $\triangleright \gamma = 0.9$  (in the second exercise also 0.5 and 0.95)
  - ▶  $T \in \{3, 5, 10, 30\}.$
  - $\sigma_{\mu} = 0.5$  and  $\sigma_{\varepsilon} = 0.25$ .
  - ▶ N = 100 (the cross-sectional dimension).
  - 1000 replications.

Dynamic panel data models

- The standard estimators (FE, RE, FD) fail to account for dynamics in the dynamic panel data models. This is due to the fact that the lagged dependent variable becomes endogenous (correlated with error term).
- The dynamic panel data (DPD) models are designed to account for this endogeneity.
- It is important when T is relatively small  $\implies$  micro data.
  - When T is large the Nickell's bias is relatively small. Which T is sufficiently large to ignore the Nickell's bias?

### The Anderson and Hsiao estimator

JAKUB MUĆK ADVANCED APPLIED ECONOMETRICS DYNAMIC PANEL DATA MODELS THE ANDERSON

◆□ ▶ ◆□ ▶ ◆三 ▶ ◆三 ▶ ● ● ● ● ● ●

# The Anderson and Hsiao estimator I

- SGH
- Anderson and Hsiao (1981) propose estimator that simply uses the IV.
- Starting point: the FD estimator:

$$\Delta y_{ti} = \gamma \Delta y_{ti-1} + \beta_1 \Delta x_{1ti} + \ldots + \beta_k \Delta x_{kti} + \Delta \varepsilon_{it}.$$
 (15)

- **Problem:**  $\Delta y_{ti-1}$  is correlated with the error term  $\Delta \varepsilon_{it} = \varepsilon_{it} \varepsilon_{it-1}$ .
- Use twice lagged level of dependent variable  $y_{it-2}$  as an instrument for  $\Delta y_{ti-1}$ . By construction,  $y_{it-2}$  is not correlated with the error term  $\Delta \varepsilon_{it}$ but is correlated with endogenous variable, i.e.  $\Delta y_{ti-1}$ .
- In general, one might use the twice lagged differences  $\Delta y_{ti-2} = y_{ti-2} y_{ti-3}$ as a valid instrument for endogenous variable  $\Delta y_{ti-1}$ . But:
  - Using  $y_{ti-2}$  as the instrumental variable  $\implies$  more data.
  - Using  $\Delta y_{ii-2}$  as the instrumental variable  $\implies$  larger asymptotic variance of estimator.
- The AH estimator delivers consistent but not efficient estimates of the parameters in the model. This is due to the fact that the IV doesn't exploit all the available moments conditions.
- The IV estimator also ignores the structure of the error component in the transformed model.
  - ▶ The autocorrelation in the first differences errors leads to inconsistency of the IV estimates.
- The IV estimates would be inconsistent when other regressors are correlated with the error term. イロト イヨト イヨト イヨト 二日

## The Arellano Bond estimator

JAKUB MUĆK ADVANCED APPLIED ECONOMETRICS DYNAMIC PANEL DATA MODELS THE ARELLANO BOND ESTIMATOR

- Arellano and Bond (1991) suggest using a GMM approach based on all available conditions.
- Starting point: the FD estimator:

$$\Delta y_{it} = \gamma \Delta y_{it-1} + \beta' \Delta x_{it} + \Delta \varepsilon_{it} \tag{16}$$

Valid instruments:

- $\blacktriangleright$  [t=2 or t=1]: no instruments,
- [t=3]: the valid instrument for  $\Delta y_{i2} = (y_{i2} y_{i1})$  is  $y_{i1}$ ,
- ▶ [t=4]: the valid instruments for  $\Delta y_{i3} = (y_{i3} y_{i2})$  is  $y_{i2}$  as well as  $y_{i1}$ ,
- ▶ [t=5]: the valid instruments for  $\Delta y_{i4} = (y_{i4} y_{i3})$  is  $y_{i3}$  as well as  $y_{i2}$  and  $y_{i1}$ ,
- [t=6]: the valid instruments for  $\Delta y_{i5} = (y_{i5} y_{i4})$  is  $y_{i4}$  as well as  $y_{i3}$ ,  $y_{i2}$  and  $y_{i1}$ ,
- ▶ [t=T]: the valid instruments for  $\Delta y_{iT-1} = (y_{iT-1} y_{iT-2})$  is  $y_{iT-2}$  as well as  $y_{iT-3}, \ldots, y_{i1}$ .
- Hence, there is a total of (T-1)(T-2)/2 available instruments or moment conditions for  $\Delta y_{it-1}$ . In general, it can be written as:

$$\mathbb{E}\left[y_{is}\left(\Delta y_{it} - \gamma \Delta y_{it-1} - \beta' \Delta x_{it}\right)\right] = 0 \quad \text{for } s = 0, \dots, t-2 \text{ and } t = 2, \dots, T$$
(17)

• Consider the following specification:

$$\Delta y_{i.} = \gamma \Delta y_{i.-1} + \Delta X_{i.\beta} + \Delta \varepsilon_{i.}, \qquad (18)$$

where

$$\Delta y_{i.} = \begin{bmatrix} \Delta y_{i2} \\ \Delta y_{i3} \\ \vdots \\ \Delta y_{iT} \end{bmatrix}, \Delta y_{i.-1} = \begin{bmatrix} \Delta y_{i1} \\ \Delta y_{i2} \\ \vdots \\ \Delta y_{iT-1} \end{bmatrix}, \Delta X_{i.} = \begin{bmatrix} \Delta x'_{i2} \\ \Delta x'_{i3} \\ \vdots \\ \Delta x'_{iT} \end{bmatrix}, \Delta \varepsilon_{i.} = \begin{bmatrix} \Delta \varepsilon_{i2} \\ \Delta \varepsilon_{i3} \\ \vdots \\ \Delta \varepsilon_{iT} \end{bmatrix}$$

• The corresponding matrix of instruments for the lagged difference:

$$W_i = \begin{bmatrix} y_{i1} & 0 & \dots & 0 \\ 0 & y_{i1}, y_{i2} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & y_{i1}, y_{i2}, \dots, y_{iT-2} \end{bmatrix},$$

Then the moment conditions can be described as:

$$\mathbb{E}\left[W_i'\Delta\varepsilon_{i.}\right] = 0\tag{19}$$

12

SGH

• Finally, the GMM estimator that takes into account the formulated moment conditions can be applied:

$$\hat{\lambda}^{GMM} = \left(G'ZS_NZ'G\right)^{-1}G'ZS_NZ'\Delta y \tag{20}$$

where

- $\hat{\lambda}^{GMM} = \left[ \hat{\gamma}^{GMM} \hat{\beta}^{GMM} \right]',$   $G = (\Delta y_{-1}, \Delta X),$   $Z = (W, \Delta X).$
- $S_N$  is the optimal weighting matrix.

• The matrix  $S_N$  is usually calculated from initial estimates, e.g., IV estimates.

$$S_N = \left(\sum_{i=1}^N Z'_{i.} \hat{e}_{i.} \hat{e}'_{i.} Z_{i.}\right)^{-1}, \qquad (21)$$

・ロト ・四ト ・ヨト ・ヨト

where  $\hat{e}_{i}$  stands for the residuals from the initial estimates.

• The above procedure refers to two-step GMM estimator. Alternatively, onestep estimator can be applied. One-step estimator takes into account the dynamic structure of the error term.

- The Arellano-Bond (AB) estimator is usually called difference GMM.
- The AB estimator deteriorates when:
  - ▶  $y_{it}$  exhibits a substantial persistence, i.e.,  $\gamma$  is close to unity.
  - the variance of unit-specific error component  $(\sigma_{\mu})$  increases relatively to the variance of the idiosyncratic error term  $(\sigma_{\varepsilon})$ .
- Note that for long panel (large T) the number of instruments increases dramatically, i.e., r = T/(T-1)/2.
- Consistency of the GMM estimator bases on the assumption that the transformed error term is not serially correlated, i.e.,  $\mathbb{E}(\Delta \varepsilon_{i,t}, \Delta \varepsilon_{i,t-2}) = 0$ .
  - ▶ It's crucially to test whether the second-order autocorrelation is zero for all periods in the sample. Conventionally, test bases on residuals from the first difference equation.

# A system GMM estimator

JAKUB MUĆK ADVANCED APPLIED ECONOMETRICS Dynamic panel data models

A SYSTEM GMM ESTIMATOR

- Blundell and Bond (1998) propose to include additional moment restrictions.
  - These additional moment restrictions are imposed on the distribution of initial values, i.e.,  $y_{i0}$ .
  - $\blacktriangleright$  This set of restrictions is important when  $\gamma$  is close to unity and/or when  $\sigma_{\mu}/\sigma_{\varepsilon}$  becomes large.
- Consider simply panel AR(1) without regressors. Then,

$$y_{i0} = \frac{\mu_i}{1 - \gamma} + \varepsilon_{i0} \quad \text{for } i = 1, \dots, N.$$
(22)

under the following assumption:

$$\mathbb{E}\left(\Delta y_{i1}\mu_i\right) = 0\tag{23}$$

• It can be show that if the above condition is satisfied then the following T-1moment conditions can be used:

$$\mathbb{E}\left[\left(y_{it} - \gamma y_{it-1}\right)\Delta y_{it-1}\right] = 0.$$
(24)

• Note that the system estimator combines the standard AB estimator and equation for levels (with the corresponding T-1 moment conditions).

イロト イヨト イヨト イヨト

■ The instrument matrix:

$$Z = \begin{bmatrix} Z^{AB} & 0 & 0 & \dots & 0 \\ 0 & \Delta y_{i2} & 0 & \dots & 0 \\ 0 & 0 & \Delta y_{i3} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & \Delta y_{iT-1} \end{bmatrix}$$
(25)

◆□▶ ◆□▶ ◆注▶ ◆注▶ ─注

where  $Z^{AB}$  is the instrument matrix from the Arellano-Bond estimator.
